### RNN/LSTM Recap

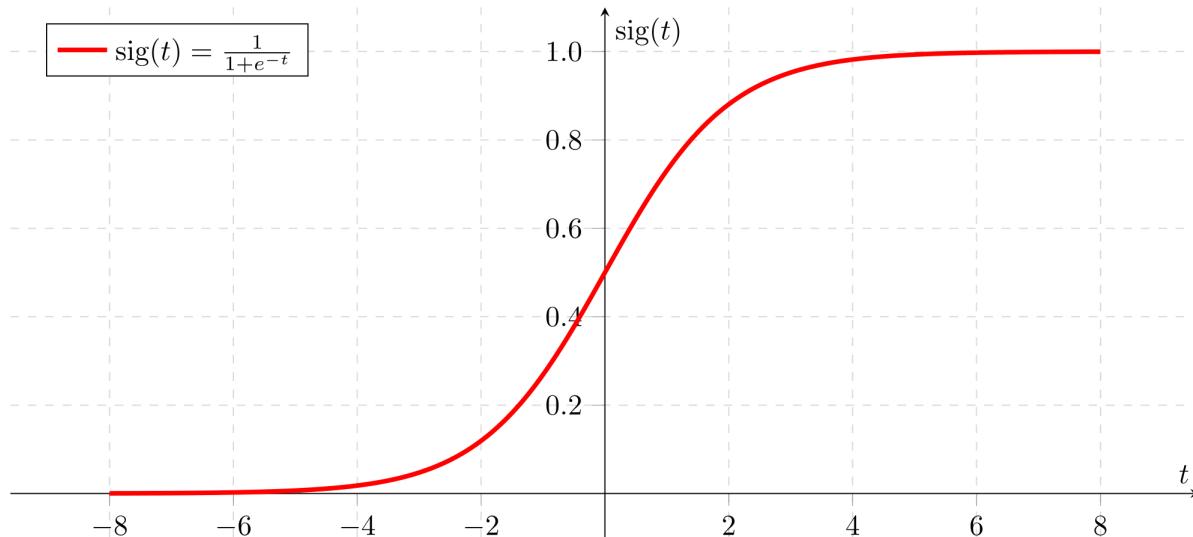

## TanH - Squashing Function

Helps maintain output between -1 & +1. If we don't have it, then after 500 iterations a big output may explode!

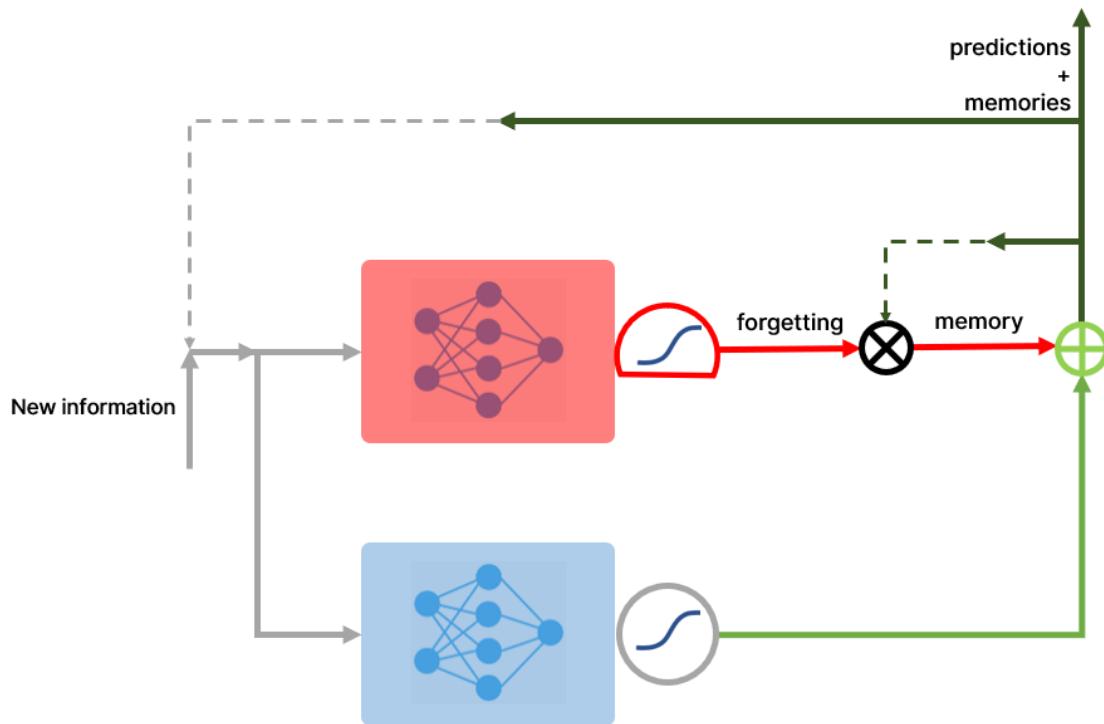

## Sigmoid - Selection Gate

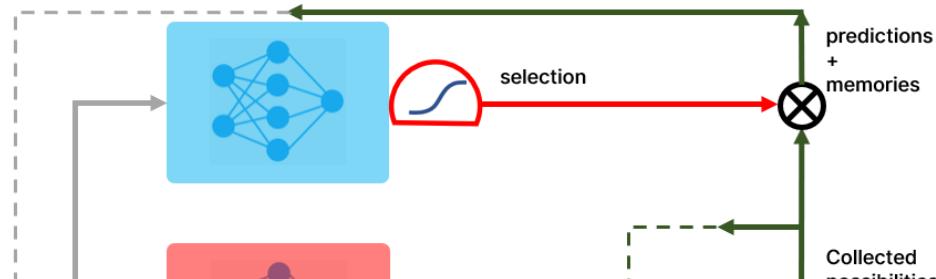

We'd like to use a function which is between 0 and 1 for this. We use sigmoid for that.

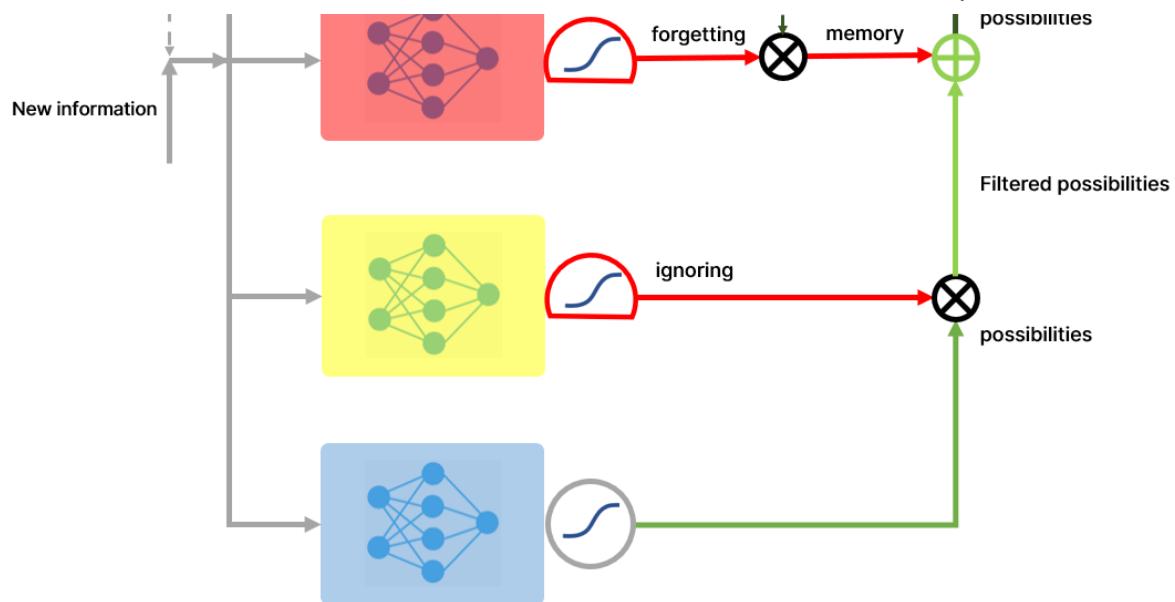

**Elementwise multiplication acts like a router, controlling what goes out and what doesn't.**

## Adding Memory to our Network

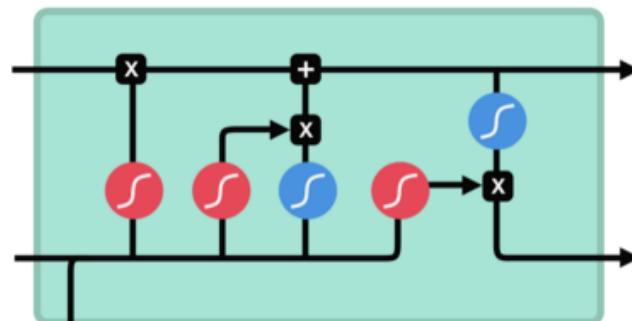

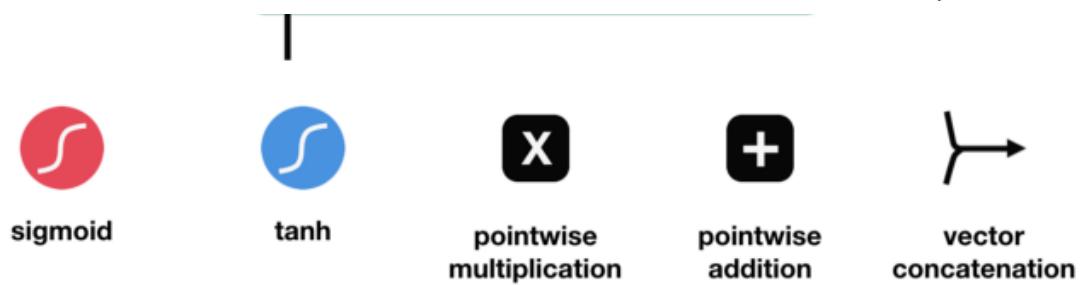

## LSTMs

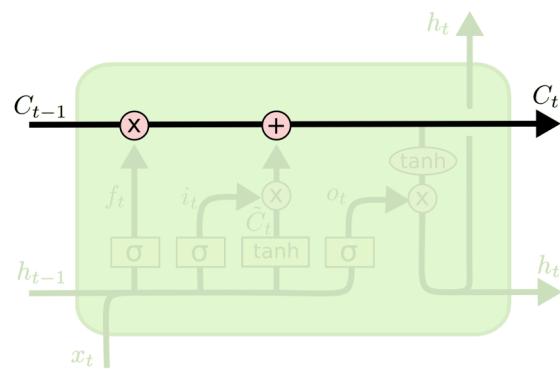

An LSTM has a similar control flow as a recurrent neural network. It processes data passing on information as it propagates forward. The differences are the operations within the LSTM's cells.

## LSTM Internals

The key to LSTMs is the cell state or memory. It is shown as the horizontal line running through the top of the diagram (and as the circular loop in our image).

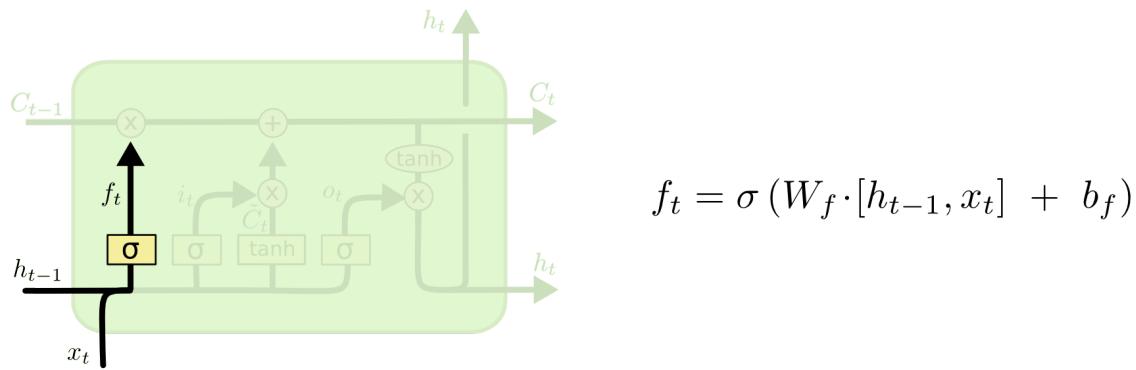

The cell-state or the memory is maintained by the forgetting gate. Unlike in RNN where will forget because of over-writes, memory in LSTM is maintained by the **forget gate** removing the un-necessary edits.

[Source \(<https://colah.github.io/posts/2015-08-Understanding-LSTMs/>\)](https://colah.github.io/posts/2015-08-Understanding-LSTMs/): You cannot get a better source than COLAH's blog on LMST/GRU etc.

Let's go through LSTM's again step-by-step:

## STEP 1 - Forget Gate

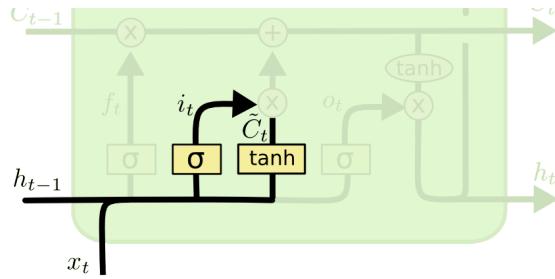

Forget the additional information which might have entered in the immediate last step, and maintain the long term information required. This is why it is called Forget Gate:

## STEP 2 - Input Gate

Not let's decide what information we want to add based on the new-input. For this, we will use 1 DNN to predict all possible values, and other **re-scores** or **filter-outs** the values, like a manager, would.

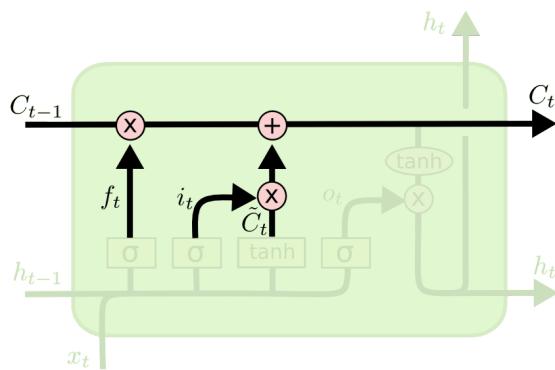

$$i_t = \sigma(W_i \cdot [h_{t-1}, x_t] + b_i)$$

$$\tilde{C}_t = \tanh(W_C \cdot [h_{t-1}, x_t] + b_C)$$

## STEP 3 - Update the Memory/Context/Cell-State

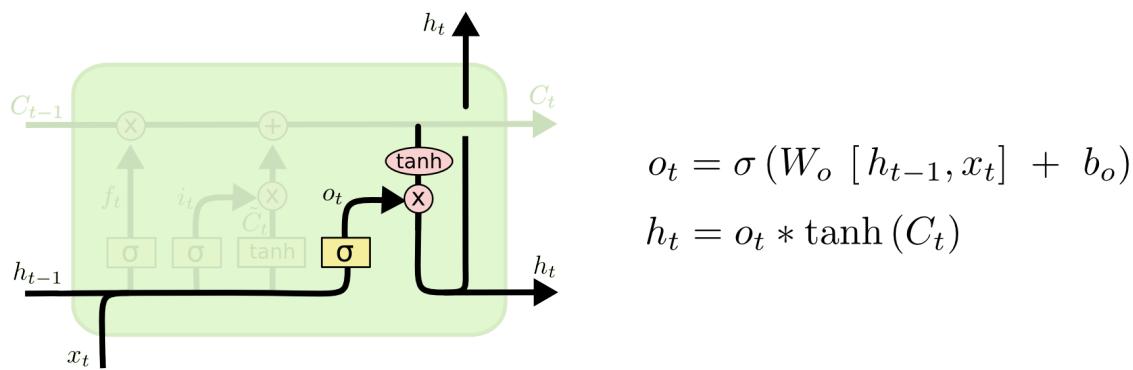

Now let's forget whatever we might have added in the last step, and add new information through the input gate.

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t$$

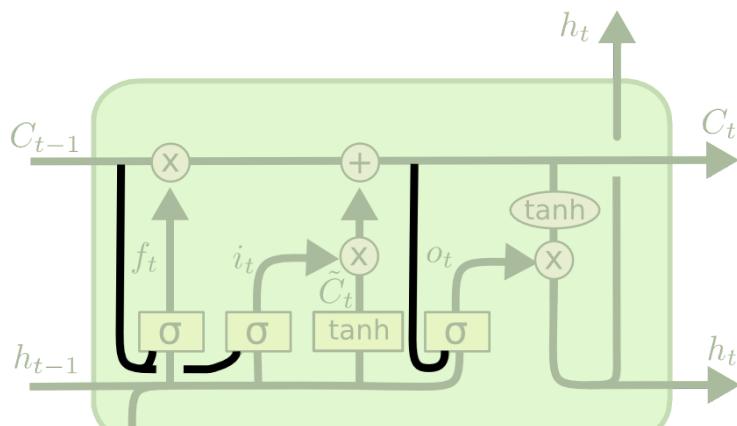

## STEP 4 - The Output

Till now we have updated our Memory/Cell-state. It is time to now provide the output. Our Memory is not our output, we need to filter things out.

## LSTM Variants

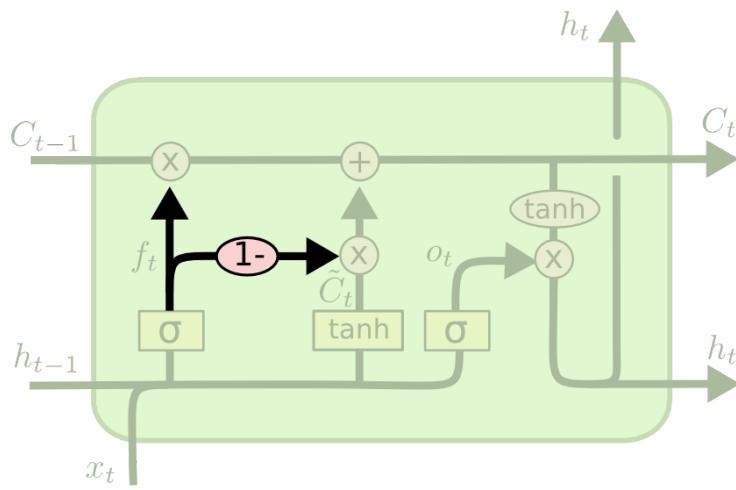

**Peephole:** Now since you have gone through simple LSTM, we can create many different variants. Look at this one called Peephole LSTM.

$$\begin{aligned}
 f_t &= \sigma(W_f \cdot [C_{t-1}, h_{t-1}, x_t] - \\
 i_t &= \sigma(W_i \cdot [C_{t-1}, h_{t-1}, x_t] - \\
 o_t &= \sigma(W_o \cdot [C_t, h_{t-1}, x_t] +
 \end{aligned}$$

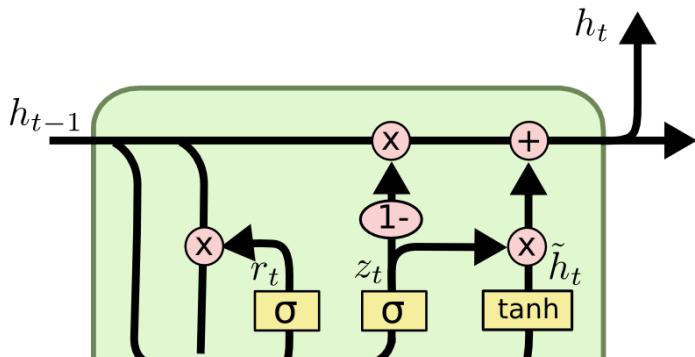

$x_t$ 

**Coupled Forget-Input LSTM:** Instead of separately deciding what to forget and what we should add, we can make those decisions together. We only forget when we're going to input something in its place. Forget and Input becomes Ying-Yang!

$$C_t = f_t * C_{t-1} + (1 - f_t) * \text{input}$$

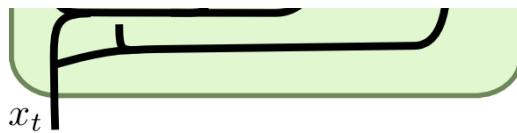

## GRU

$$z_t = \sigma (W_z \cdot [h_{t-1}, x_t])$$

$$r_t = \sigma (W_r \cdot [h_{t-1}, x_t])$$

$$\tilde{h}_t = \tanh (W \cdot [r_t * h_{t-1}, x_t])$$

$$h_t = (1 - z_t) * h_{t-1} + z_t * \tilde{h}$$

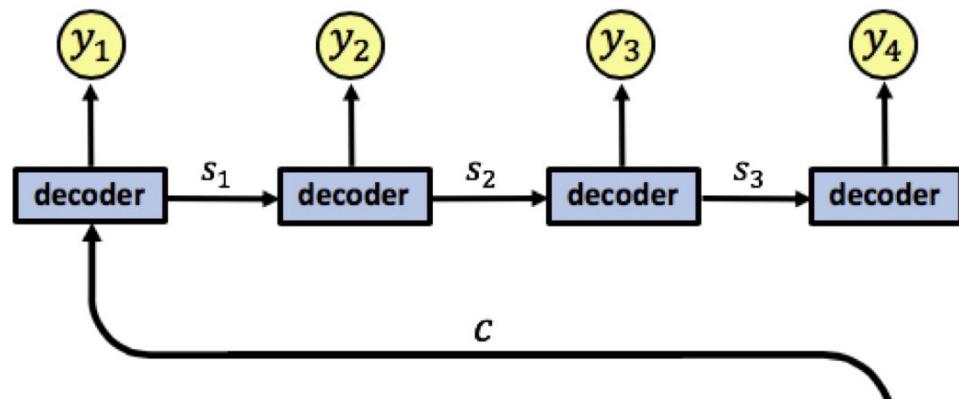

A slightly more dramatic variant on the LSTM is the **Gater Recurrent Unit** or GRU.

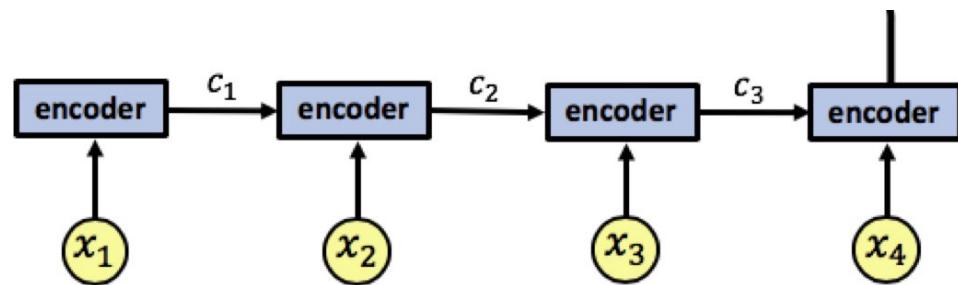

- It combines the forget and input gates into a single "update gate".
- It also merges the cell state and hidden state
- It updates the memory twice, the first time (using old state and new input, called **Reset Gate**) and the second time (as final output).
- Old cell state or hidden state (with input) is used for its own update as well as for deciding

GRU has been growing increasingly popular and is a default alternative for LSTMs.

## Encoder-Decoder Architecture in RNN/LSTMs

The RNN encoder-decoder architecture looks like this [[source](#) (<https://medium.com/datadriveninvestor/attention-in-rnns-321fbcd64f05>)]

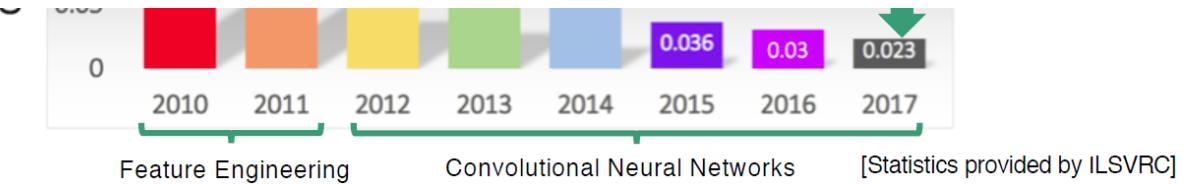

The RNN encoder has an input sequence  $x_1, x_2, x_3, x_4$ . We denote the encoder states by  $c_1, c_2, c_3$ . The encoder outputs a single output vector  $c$  which is passed as input to the decoder. Like the encoder, the decoder is also a single-layered RNN, we denote the decoder states by  $s_1, s_2, s_3$  and the network's output by  $y_1, y_2, y_3, y_4$ .

A problem with this architecture lies in the fact that the decoder needs to represent the entire input sequence  $x_1, x_2, x_3, x_4$  as a single vector  $c$ , which can cause information loss. Moreover, the decoder needs to decipher the passed information from this single vector, a complex task in itself.

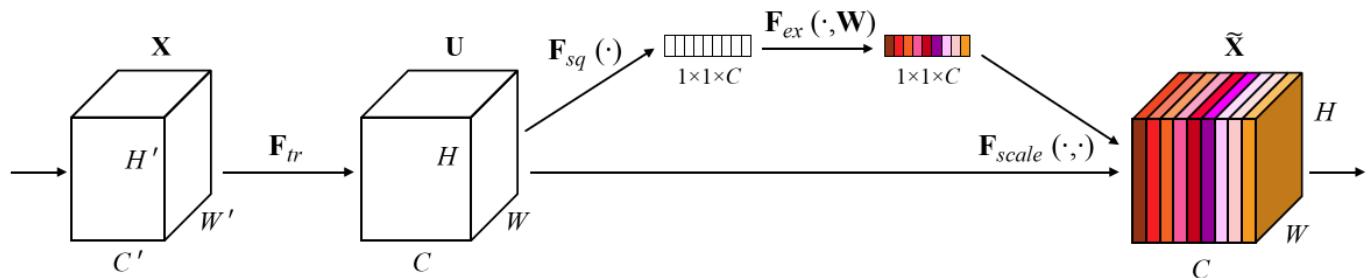

## RNN/LSTM with an Attention Mechanism

First let's take a look at a variant of ResNet called [SENet](https://arxiv.org/pdf/1709.01507.pdf) (<https://arxiv.org/pdf/1709.01507.pdf>)..

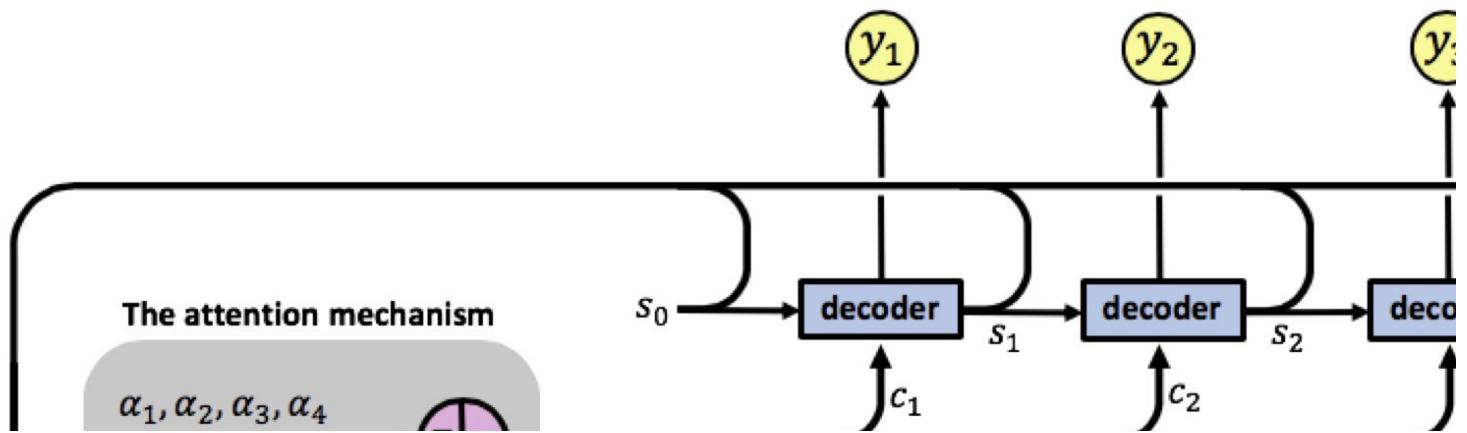

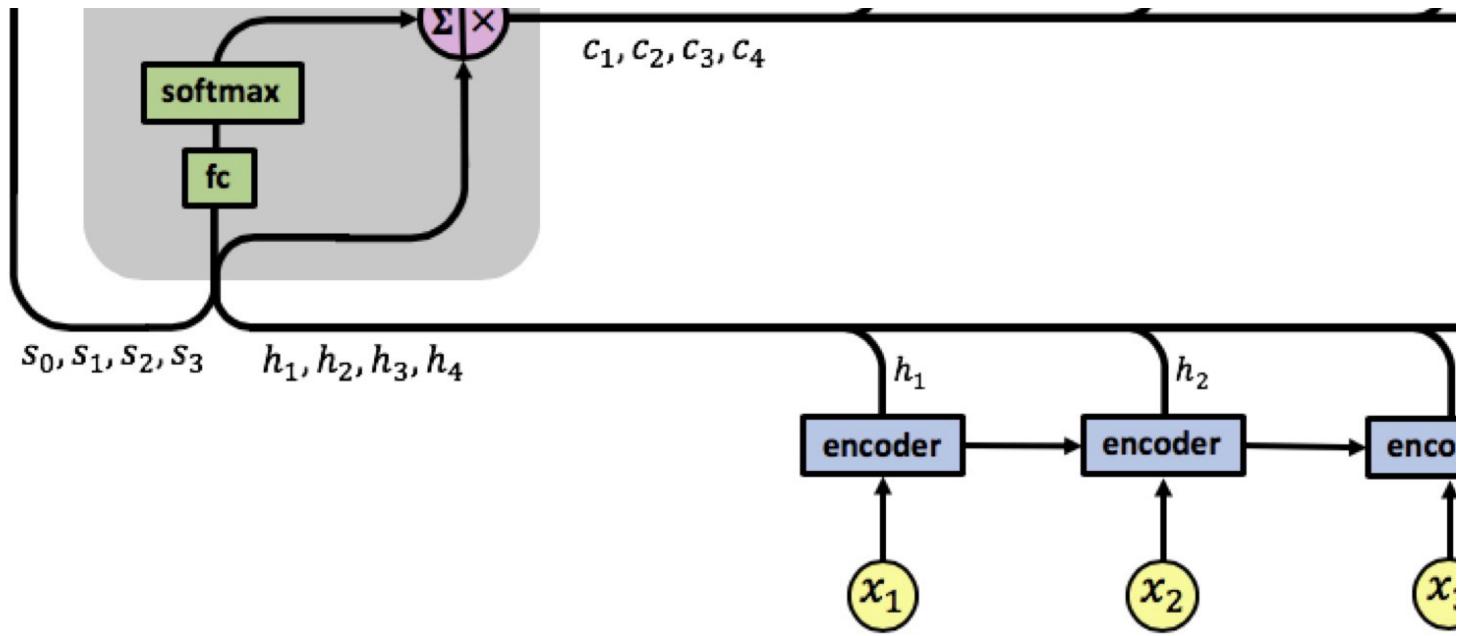

## Squeeze and Excitation Block

An attention RNN/LSTM looks like this:

Our attention model has a single RNN encoder, again with 4-time steps. We denote the encoder's input vectors by  $x_1, x_2, x_3, x_4$  and the output vectors by  $h_1, h_2, h_3, h_4$ .

The attention mechanism is located between the encoder and the decoder.

Its output is composed of the encoder's input vectors  $h_1, h_2, h_3, h_4$  and the states of the decoder  $s_0, s_1, s_2, s_3$ , the attention's output is a sequence of vectors called **context vectors** denoted by  $c_1, c_2, c_3, c_4$ .

## The Context Vector

The context vectors enable the decoder to focus on certain parts of the input when predicting its output.

Each context vector is a weighted sum of the encoder's output vector  $h_1, h_2, h_3, h_4$

Each vector  $h_i$  contains information about the **whole input sequence up to that moment with a strong focus on the  $i^{th}$  stage.**

The vectors  $h_1, h_2, h_3, h_4$  are scaled by weights  $\alpha_{ij}$  capturing the degree of relevance of input.

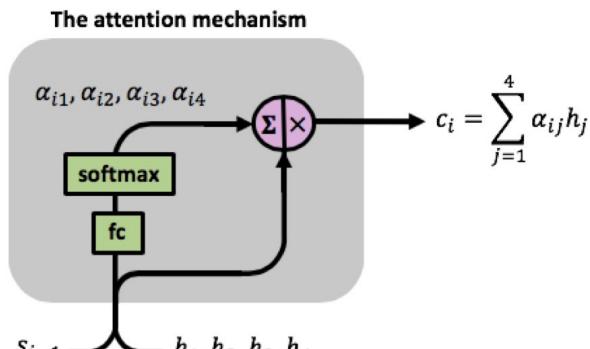

The context vectors  $c_1, c_2, c_3, c_4$  are given by:

$$c_{ij} = \sum_{j=1}^4 \alpha_{ij} h_j$$

The attention weights are learned using an additional fully connected shallow network, denoted by **fc**, this is where the  $s_0, s_1, s_2, s_3$  part of the attention mechanism's input comes into play. Computation of the attention weights are given by:

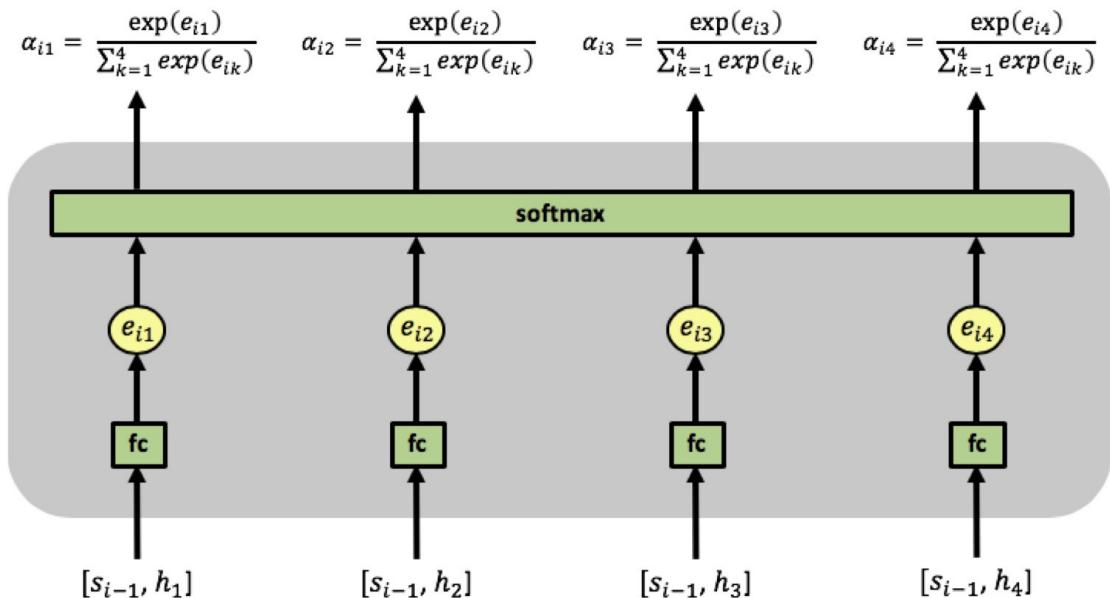

$$\alpha_{ij} = \frac{\exp(fc(s_{i-1}, h_j))}{\sum_{k=1}^4 \exp(fc(s_{i-1}, h_k))}$$

The attention weights are learned using the attention fully-connected network and a softmax function:

As can be seen in the image above, the fc receives the concatenated vectors  $[s_{i-1}, h_i]$  as the input at time step i. The network has a single **fc** layer, the outputs of the layer are passed through a softmax function computing the attention weights

Notice that we are using the **same** fully-connected network for all the concatenated pairs  $[s_0, h_1], [s_0, h_2], [s_0, h_3], [s_0, h_4]$

The fc network is trained along with the encoder and decoder using backpropagation, the RNN's prediction error terms are backpropagated backward through the decoder, then through the fc attention network and from there to the encoder.

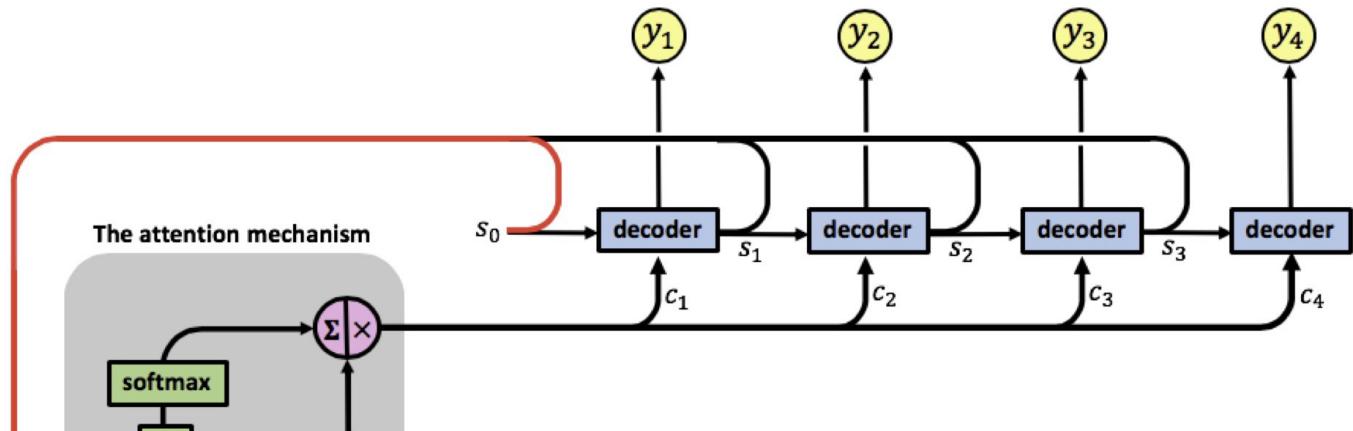

**By letting the decoder have an attention mechanism, we relieve the encoder from having to encode all information in the input sequence into a single vector.**

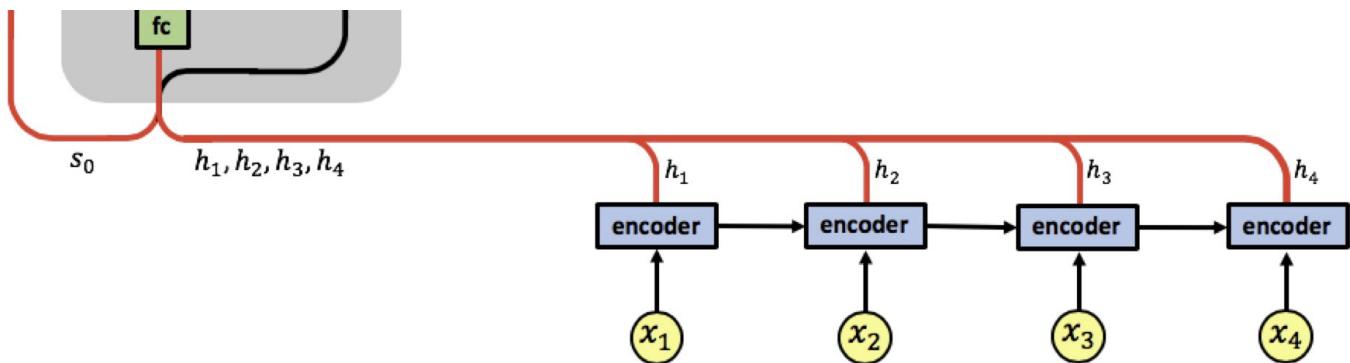

## Computing Attention Weights and Context Vectors

Let's go over a detailed example:

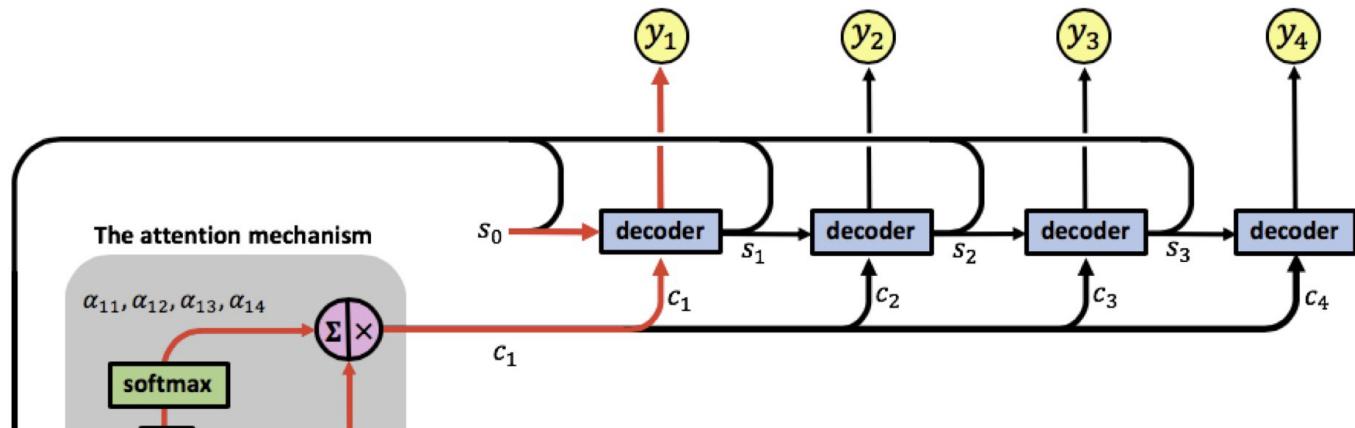

The first act performed is the computation of vectors  $h_1, h_2, h_3, h_4$  by the encoder.

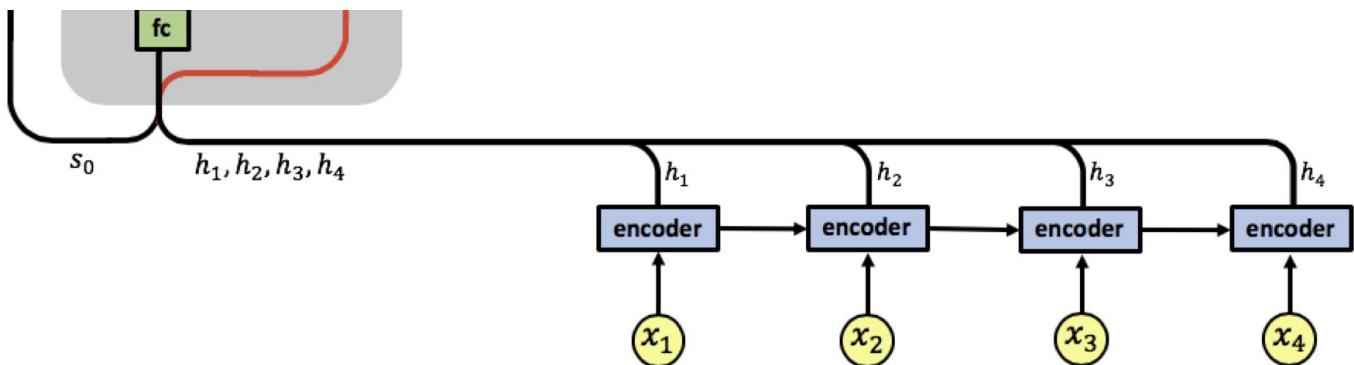

These are then used as inputs of the attention mechanism. This is where the decoder is first involved by inputting its initial state vector and we have the **first attention input sequence**  $[s_0, h_1], [s_0, h_2], [s_0, h_3], [s_0, h_4]$

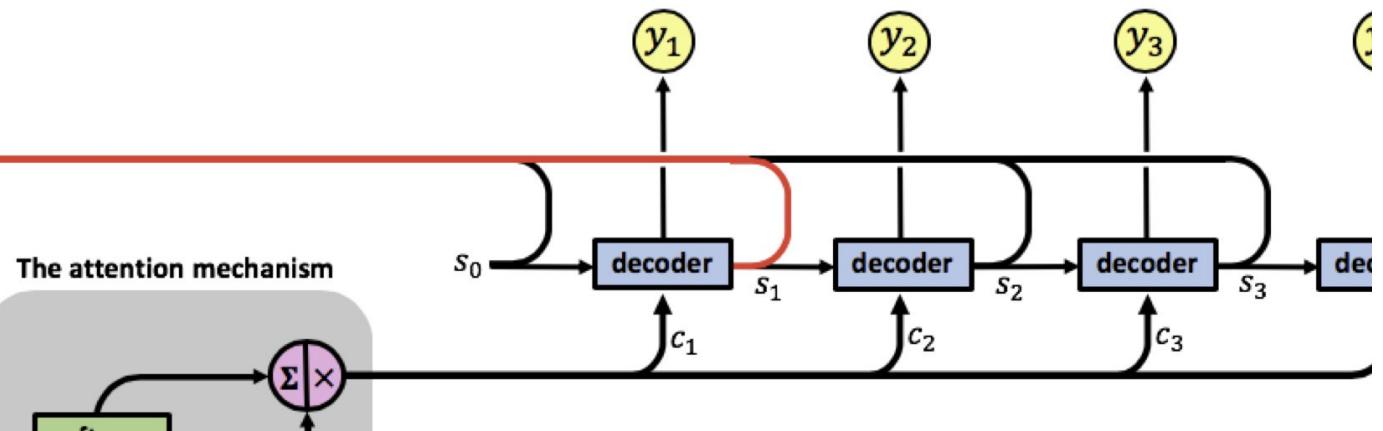

The attention mechanism computes the first set of attention weights enabling the computation of the first context vector  $c_1$ . The decoder now uses  $\text{softmax}(c_1)$  and computes the first RNN output  $y_1$ .

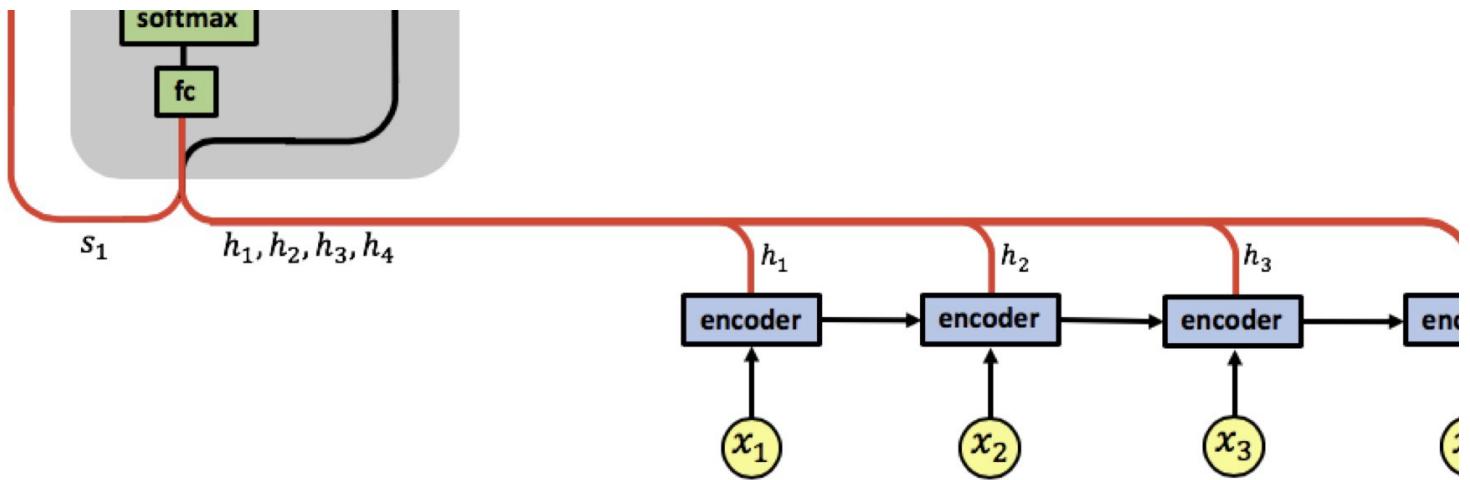

At the following step, the attention mechanism has as input the sequence

$$[s_1, h_1], [s_1, h_2], [s_1, h_3], [s_1, h_4]$$

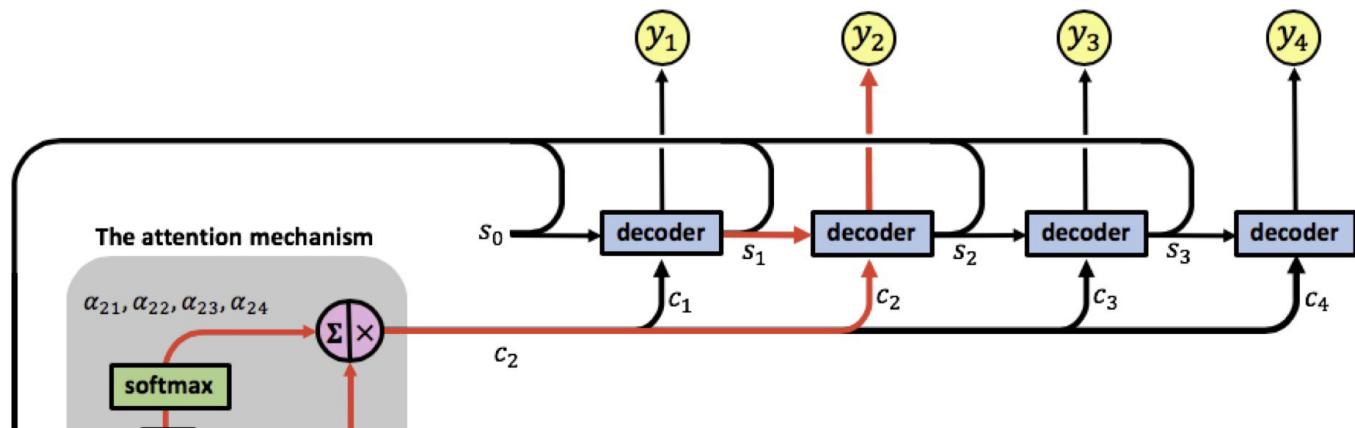

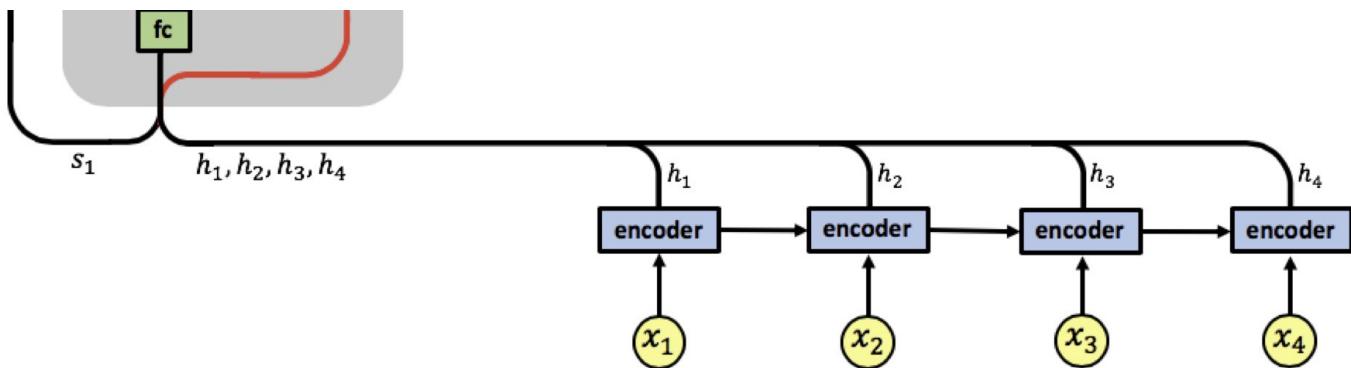

It computes a second set of weights enabling computation of the second context vector  $c_2$ . The decoder uses

$$[s_1, c_2]$$

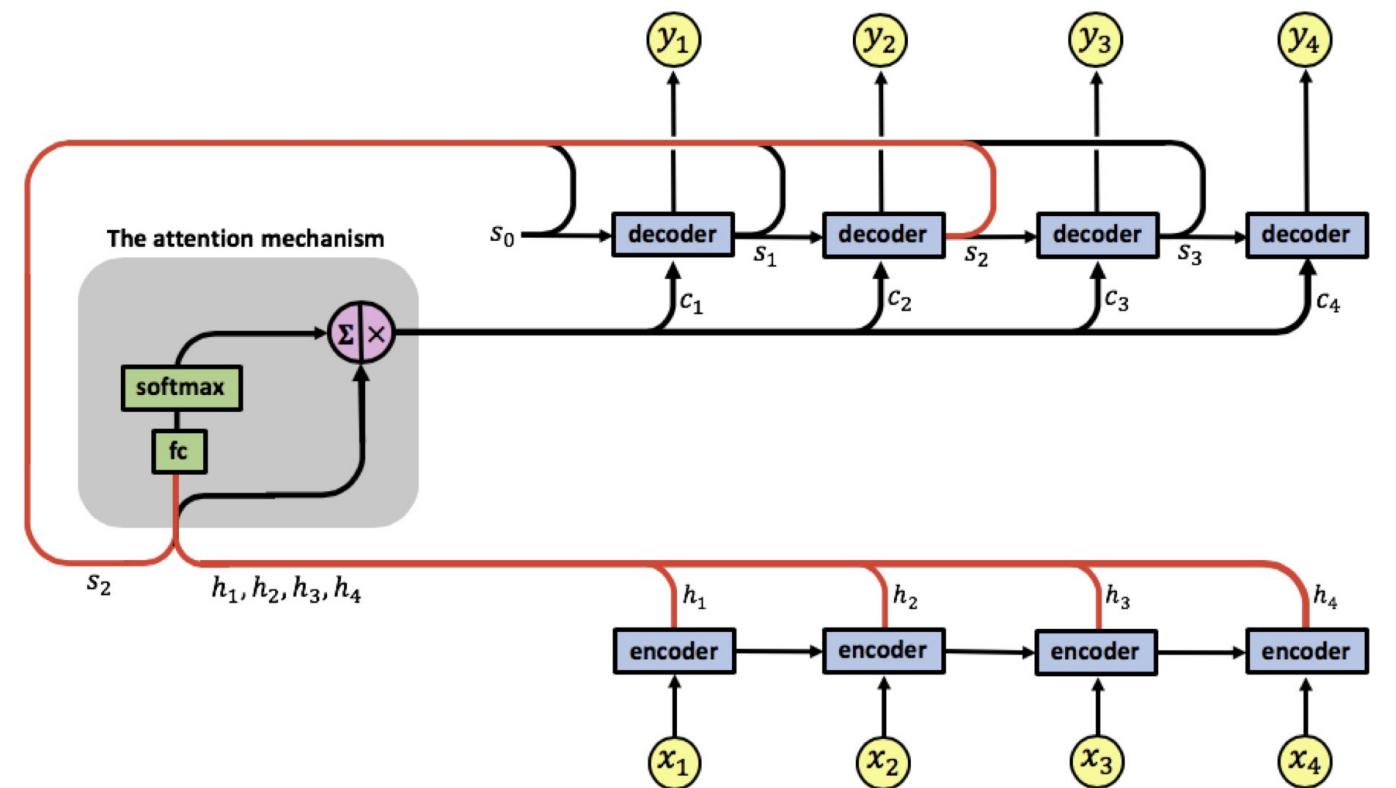

and computes the second RNN output

$$y_2.$$

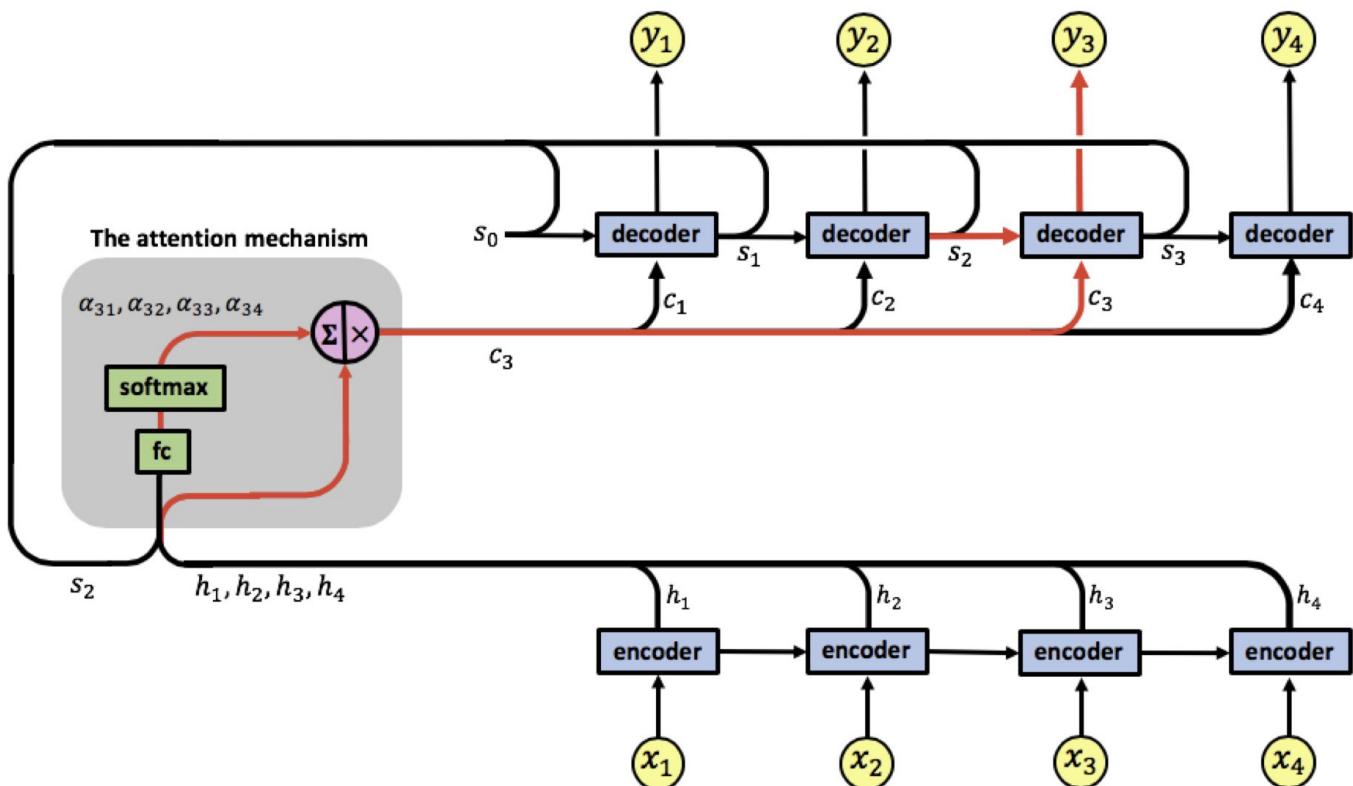

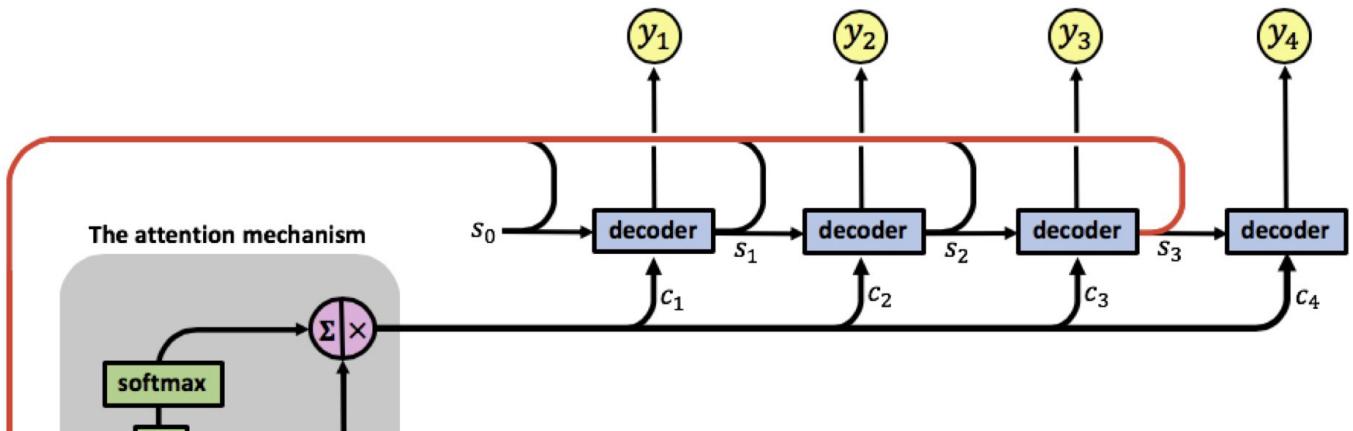

This next step should be clear:

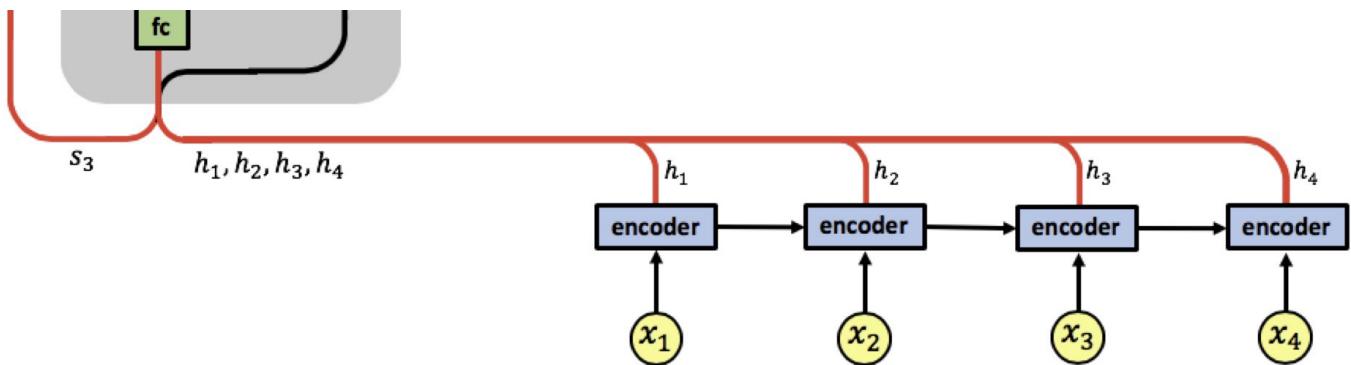

then this:

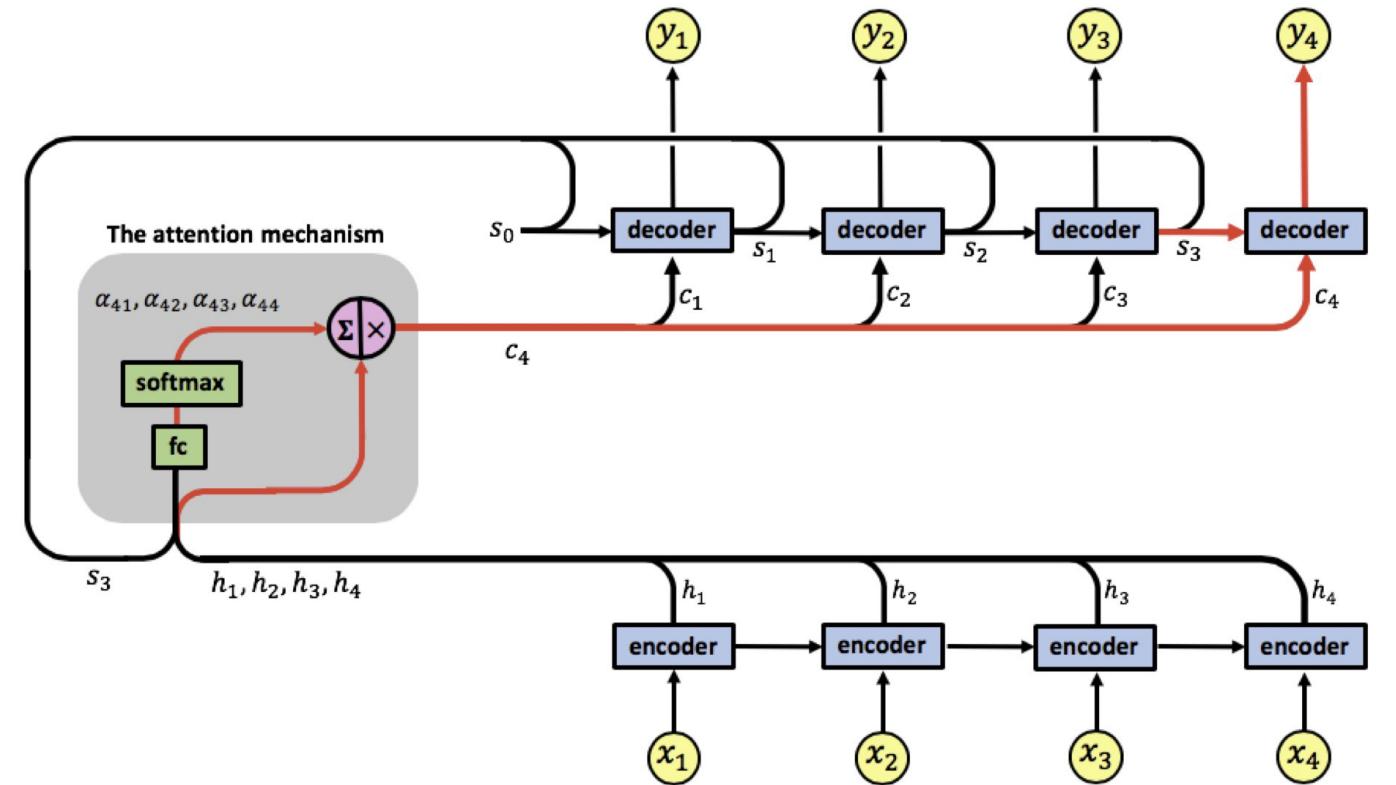

Then this:

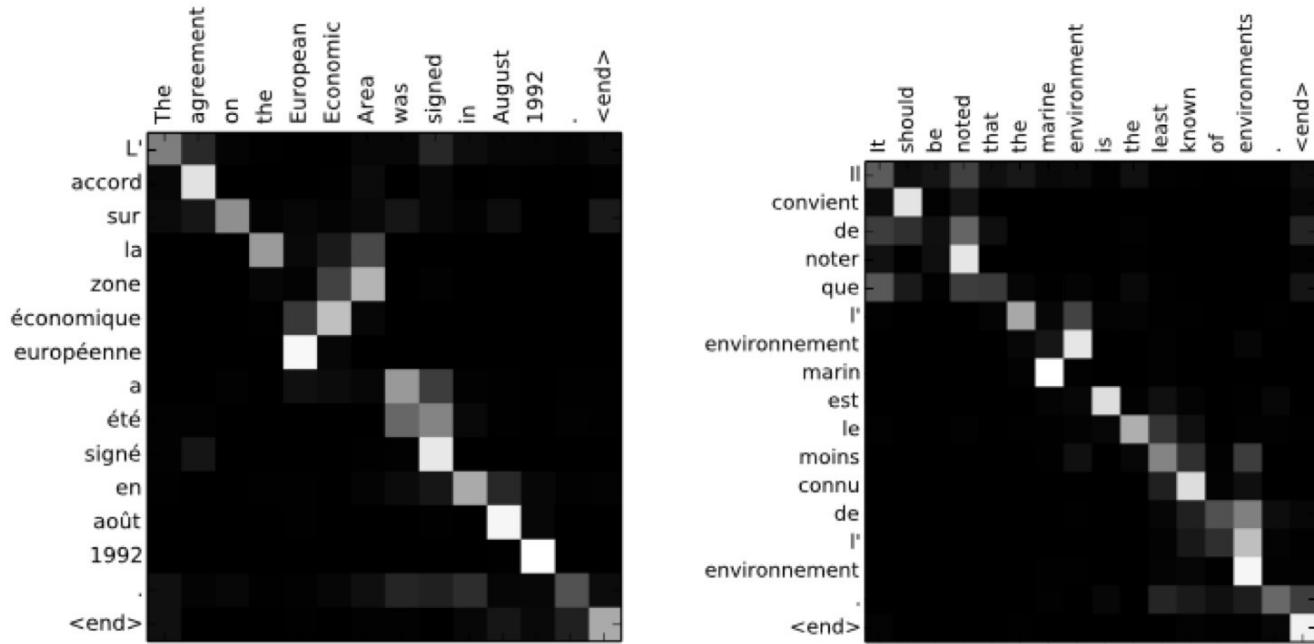

and finally this:

In the end, we have consumed 4 vectors, and with attention focused on a specific vector, we should and then made the prediction for each step.

Below are two alignments found by the attention RNN. The x-axis and y-axis of each plot correspond to the words in the source sentence (English) and the generated translation (French), respectively.

Each pixel shows the weight  $\alpha_{ij}$  of the  $j^{th}$  source word and the  $i^{th}$  target word, in grayscale (0: black, 1: white).

Better illustrations can be found here: <https://distill.pub/2016/augmented-rnns/>

## Assignment

1. Look at this [file](https://bastings.github.io/annotated_encoder_decoder/) ([https://bastings.github.io/annotated\\_encoder\\_decoder/](https://bastings.github.io/annotated_encoder_decoder/))
2. Re-implement this and move to lambda. Provide the option to provide German text and get English text back.
